

(a) A de novo flow

composition *and* geometry from one model

No bond labels anywhere. Reversing the same ODE gives $\log p_\theta(x | c)$.

(b) Teacher energy values

K displaced geometries of *one* parent

A universal neural potential over 83 elements supplies every value. Only the values are used.

(c) The value term

$$\mathcal{L}_{\text{ours}} = \mathcal{L}_{\text{FM}} + \lambda_E \mathcal{L}_{\text{value}}$$
$$\mathcal{L}_{\text{value}} = \text{Var}_k [\log p_\theta(x_k | c) + E_k/kT]$$

one added term; the free constant absorbs $\log Z$

$$\mathcal{L}_{\text{value}} = 0 \text{ within a group} \iff \log p_\theta = -E_k/kT + b$$

(d) What this identifies

two disconnected groups, *same* composition c

Nothing relates A to B , so $b_B - b_A$
and the relative mass are not identified.
